8.1 Stellar Properties

Consider two stars A and B with properties ...

Name	Spectral type	$m_B \text{ (mag)}$	$m_V \text{ (mag)}$	Diameter $(\times 10^{-3}")$	Parallax (")	Mass (M_{\odot})
Star A	M2 Ia	2.27	0.42	43.43	0.00451	19.6
Star~B	M2 V	8.96	7.52	1.43	0.393	0.46

(a) Distances

$$d(\text{pc}) = \frac{1}{\theta_{\text{parallax}}(")}$$

$$d_A = \frac{1}{0.00451} \approx 221.72 \text{ pc}, \qquad d_B = \frac{1}{0.393} \approx 2.544 \text{ pc}$$

(b) Radii

From the small-angle relation

$$\theta_{\text{diam}} = \frac{2R}{d} \qquad \Rightarrow \qquad R = \frac{\theta_{\text{diam}}}{2} d$$

with θ in radians (1" = 4.848×10^{-6} rad):

$$R_A = \frac{43.43 \times 10^{-3}}{2 \times 206265} \,(221.72)(3.086 \times 10^{16}) \approx 7.20 \times 10^{11} \,\,\mathrm{m}$$

$$R_B = \frac{1.43 \times 10^{-3}}{2 \times 206265} (2.544)(3.086 \times 10^{16}) \approx 2.72 \times 10^8 \text{ m}$$

Expressed in solar radii ($R_{\odot} = 6.96 \times 10^8$ m):

$$R_A \approx 1.035 \times 10^3 R_{\odot}, \qquad R_B \approx 0.391 R_{\odot}$$

(c) Surface Gravity

$$g = \frac{GM}{R^2}$$

$$M_A = 19.6 \, M_{\odot} = 3.89 \times 10^{31} \,\mathrm{kg}, \qquad M_B = 0.46 \, M_{\odot} = 9.15 \times 10^{29} \,\mathrm{kg}$$

$$g_A = \frac{6.67 \times 10^{-11} (3.89 \times 10^{31})}{(7.20 \times 10^{11})^2} \approx 5.0 \times 10^{-3} \,\mathrm{m/s^2}$$

$$g_B = \frac{6.67 \times 10^{-11} (9.15 \times 10^{29})}{(2.72 \times 10^8)^2} \approx 8.2 \times 10^2 \,\mathrm{m/s^2}$$

(d) Luminosity Class Comparison

We expect the main-sequence dwarf (V) to have much higher surface gravity than the supergiant (Ia). Indeed, $g_B \gg g_A$, consistent with their classifications.

(e) Temperatures

Using

$$B - V = m_B - m_V (13.35)$$

and

$$T \approx \frac{9000 \text{ K}}{(B-V) + 0.93}$$
 (13.36)

$$T_A = \frac{9000}{(2.27 - 0.42) + 0.93} \approx 3.24 \times 10^3 \text{ K}, \qquad T_B = \frac{9000}{(8.96 - 7.52) + 0.93} \approx 3.80 \times 10^3 \text{ K}$$

(f) Luminosities

From the Stefan–Boltzmann law:

$$L = 4\pi R^2 \sigma_{\rm SB} T^4$$

$$L_A = 4\pi (7.20 \times 10^{11})^2 (5.67 \times 10^{-8}) (3.24 \times 10^3)^4 \approx 4.06 \times 10^{31} \text{ W}$$

$$L_B = 4\pi (2.72 \times 10^8)^2 (5.67 \times 10^{-8}) (3.80 \times 10^3)^4 \approx 1.10 \times 10^{25} \text{ W}$$

(g) H-R Diagram Location

Star A: very cool, extremely luminous \rightarrow upper right of the H–R diagram (red supergiant). Star B: cooler main-sequence dwarf \rightarrow lower right region (red dwarf). Both positions are consistent with their spectral classifications.

Name	Distance (pc)	Radius (m)	Radius (R_{\odot})	g (m/s ²)	Temp (K)	L_{tot} (W)
Star A	221.72	7.20×10^{11}	1.04×10^{3}	5.0×10^{-3}	3.24×10^{3}	4.06×10^{31}
Star B	2.544	2.72×10^{8}	3.91×10^{-1}	8.2×10^{2}	3.80×10^{3}	1.10×10^{25}

8.2 Stellar main sequence lifetimes

Given \dots

$$N_H = \frac{M}{m_p} \tag{15.52}$$

$$E_{fus} = \frac{N_h}{4} \Delta E \tag{15.53}$$

$$t_{fus} = \frac{E_{fus}}{L} \tag{15.54}$$

We can derive ...

$$t_{fus} = \frac{1}{L} \frac{1}{4} \frac{\Delta E}{1} \frac{M}{m_p}$$

$$t_{fus} = \frac{\Delta E \times M}{4L \times m_p}$$

Where \dots

$$\Delta E = 4.1 \times 10^{-12} \text{J}, \qquad m_p = 1.67 \times 10^{-27} \text{kg}$$

a) High-Mass

 $\mathrm{Given}\,\ldots$

$$M = 100 M_{\odot} \approx 1.989 \times 10^{32} \text{kg}, \qquad L = 10^6 L_{\odot} \approx 3.83 \times 10^{32} \text{W}$$
$$t_{fus} = \frac{4.1 \times 10^{-12} \text{J} \times 1.989 \times 10^{32} \text{kg}}{4(3.83 \times 10^{32} \text{W}) \times 1.67 \times 10^{-27} \text{kg}} \approx 3.187 \times 10^{14} \text{s}$$

b) Low-mass

Given \dots

$$M = .5M_{\odot} \approx 9.945 \times 10^{29} \text{kg}, \qquad L = .1L_{\odot} \approx 3.83 \times 10^{25} \text{W}$$
$$t_{fus} = \frac{4.1 \times 10^{-12} \text{J} \times 9.945 \times 10^{29} \text{kg}}{4(3.83 \times 10^{25} \text{W}) \times 1.67 \times 10^{-27} \text{kg}} \approx 1.58 \times 10^{19} \text{s}$$

8.3

8.4 Extra Credit

a)

The parallax error would affect its location on the y-axis. This is because the parallax would affect the distance measured, which in turn effect the absolute luminosity, hence shifting the location on the y-axis. ¹

b)

Given \dots

$$d = \frac{1}{\theta_{par}} \qquad F = \frac{L_{abs}}{4\pi d^2}$$

We can find the difference as ...

$$\frac{L_{\rm meas}}{L_{\rm true}} = \left(\frac{d_{\rm meas}}{d_{\rm true}}\right)^2 = \left(\frac{1}{0.9}\right)^2 = 1.234\dots$$

c)

$$\approx 23\%_{error}$$

This means that the L value on the y-axis of the HR diagram should be 23% brighter, meaning the star should be further ${\bf up}$ on the HR diagram.

 $^{^1}$ It could also affect the x-axis through redshift + Hubble const, but if a parallax error is that big you might have bigger problems.
